J. Thomas & L. Schneider WS 2021/22

General constraints for code submissions Please adhere to these rules to make our and your life easier! We will deduct points if your solution does not fulfill the following:

- If not stated otherwise, we will use exclusively Python 3.6.
- If not stated otherwise, we expect a Python script, which we will invoke exactly as stated on the exercise sheet.
- Your solution exactly returns the required output (neither less nor more) you can implement a --verbose option to increase the verbosity level for developing.
- Add comments and docstrings, so we can understand your solution.
- (If applicable) The README describes how to install requirements or provides addition information.
- (If applicable) Add required additional packages to requirements.txt. Explain in your README what this package does, why you use that package and provide a link to it's documentation or GitHub page.
- (If applicable) All prepared unittests have to pass.
- (If applicable) You can (and sometimes have to) reuse code from previous exercises.

In this exercise you will learn how to run your NAS optimization algorithms on NAS-Bench-101. To avoid that you waste too much time training the sampled architectures, we will not optimize the actual benchmark but instead use a tabular benchmark. Refer to "NAS-Bench-101: Towards Reproducible Neural Architecture Search" for more details about the search space and encoding.

In NAS-Bench-101 every CNN architecture in the cell search space was trained and evaluated 3 independent times. This was done for 4 different budgets (training epochs), however here we will only use the results for the highest budget (108 epochs). The results are compiled into a database, such that we can simply look up the performance of a hyperparameter configuration instead of training it from scratch.

To get access to this weeks repository use the following link: https://classroom.github.com/g/Lkh261Aa.

1. Getting started with NAS-Bench-101

[2 points]

NASBench_example.py shows how we can load the benchmark together with the configuration space. Before running this script make sure you have installed all the dependencies (including tensorflow, pytorch, nasbench, etc.) as shown in setup.sh. To execute the setup run bash setup.sh. Each hyperparameter configuration is encoded as a Configuration object and we can easily convert it to a numpy array or a dictionary. Note that, if we convert it to a numpy array, all values are normalized to be in [0,1].

If we evaluate a hyperparameter configuration, we get the validation error and the time it had taken to train this configuration. When we generated this benchmark, we evaluated each hyperparameter configuration 4 times, and, for every table lookup, we pick one of these 4 trials uniformly at random. This simulates the typical noise that comes with hyperparameter optimization problems.

Here you will just have to run python NASBench_example.py > logs/log.txt and push the resulting log.txt to your Github repository.

2. Blackbox optimization on NAS-Bench-101

[12 points]

In this exercise you will have to run the command python main.py which will execute Random Search (RS), Regularized Evolution (RE) and Non-regularized Evolution (non-RE) on NAS-Bench-101. But before running this command you will have to fill the missing code in optimizers.py.

(a) In the NASOptimizer base class you will have to implement two methods which return a sampled configuration (architecture in this case) from the configuration space, and that query the validation + runtime of a specific configuration and update the incumbent trajectory.

[4pt.]

[3pt.]

Your implementation should satisfy the test in test_nb_101.py::TestRS.

(b) Now you will have to implement RE based on the pseudocode presented. non-RE keeps a population of architectures and each time it does an update, it discards the oldest architecture configuration present in the current population.

Your implementation should satisfy the test in test_nb_101.py::TestRE.

(c) Afterwards, you will have to implement non-RE based on the pseudocode presented in Slide 9, [3pt.] Topic 3. Non-RE discards the worst architecture configuration present in the current population. Everything else is the same as RE.

Your implementation should satisfy the test in test_nb_101.py::TestNonRE.

(d) Now you are ready to run python main.py. It runs by default RS, RE and non-RE by default 20 independent times for 100 function evaluations (n_iters). You may change their values if you want. After the optimization is finished, a plot logs/plot.png will be generated. You will have to push this plot to your Github repository. **NOTE:** main.py should run on a CPU machine in less than a minute (with the default arguments).

[2pt.]

3. Code Style

[1 point]

On every exercise sheet we will also make use of pycodestyle¹ to adhere to a common python standard. Your code will be automatically evaluated on every push and you will be informed if the test fails. To check it locally, first run pip install pycodestyle and then run pycodestyle --max-line-length=120 src/ to check your source file folder. Alternatively run make checkstyle
